

1. Here are two plane graphs,  $\Gamma_1$  and  $\Gamma_2$ , respectively:

- List the number of vertices, edges, and faces for both  $\Gamma_1$  and  $\Gamma_2$ .
- List the degrees of all the vertices of both  $\Gamma_1$  and  $\Gamma_2$ .
- List the degrees of all the faces (i.e., the number of edges incident with, or bounding, each face) of both  $\Gamma_1$  and  $\Gamma_2$ .
- Draw the duals  $\Gamma_1^*$  and  $\Gamma_2^*$ .
- Repeat 1a–1c for  $\Gamma_1^*$  and  $\Gamma_2^*$ .
- Conclude that  $\Gamma_1$  and  $\Gamma_2$  are “basically the same graph” but  $\Gamma_1^*$  and  $\Gamma_2^*$  are “structurally different.”

1a. Both have 6 vertices, 10 edges, and 6 faces.

1b. The degrees of the vertices for both  $\Gamma_1$  and  $\Gamma_2$  are the same:

vertex	<i>u</i>	<i>v</i>	<i>w</i>	<i>x</i>	<i>y</i>	<i>z</i>
degree	2	4	4	4	3	3

1c. The degrees of the faces for  $\Gamma_1$  are:

face	<i>uvw</i>	<i>vxw</i>	<i>vxy</i>	<i>wxz</i>	<i>xyz</i>	<i>uvyzw</i>
degree	3	3	3	3	3	5

The degrees of the faces for  $\Gamma_2$  are:

face	<i>uvw</i>	<i>vyz</i> <i>w</i>	<i>vxy</i>	<i>xyz</i>	<i>wxz</i>	<i>uvxw</i>
degree	3	4	3	3	3	4

1d. Here are  $\Gamma_1^*$  and  $\Gamma_2^*$ , superimposed over  $\Gamma_1$  and  $\Gamma_2$ , respectively:

1e. Both have 6 vertices, 10 edges, and 6 faces. Notice, though, that the 6 vertices of the duals correspond to the 6 faces of the originals, and vice-versa.

For  $\Gamma_1^*$ :

vertex	<i>a</i>	<i>b</i>	<i>c</i>	<i>d</i>	<i>e</i>	<i>f</i>
degree	3	3	3	3	3	<b>5</b>
face	<i>af</i>	<i>acdf</i>	<i>bcde</i>	<i>bef</i>	<i>def</i>	<i>acbf</i>
degree	2	4	4	3	3	4

For  $\Gamma_2^*$ :

vertex	$a$	$b$	$c$	$d$	$e$	$f$
degree	3	4	3	3	3	4
face	$af$	$abef$	$bde$	$bcd$	$cdef$	$abcf$
degree	2	4	3	3	4	4

1f. It is easy to see that  $\Gamma_1 \cong \Gamma_2$ . Basically,  $\Gamma_2$  is obtained from  $\Gamma_1$  by grabbing the vertex  $x$  and pulling it out to the right.

The reason  $\Gamma_1^* \not\cong \Gamma_2^*$  is that  $\Gamma_1^*$  has a vertex of degree 5 but  $\Gamma_2^*$  doesn't. So there is *no way*  $\Gamma_1^*$  can be deformed into  $\Gamma_2^*$ , since the degrees of the vertices don't change under any deformation.

What this example shows is that two graphs that are “structurally the same” (*isomorphic*) can have duals that are not. So, it only makes sense to talk about duals of plane graphs and not in the more general context of planar graphs.
